### ABSTRACT

**Introduction:** Patients in Geriatric Palliative Care (GPC) complain of pain and opioids are the drugs used to manage it. This study aims to understand the sociodemographic, clinical and opioid use characteristics of GPC patients in a public hospital in the Federal District of Brazil.

**Methods:** This is a cross-sectional approach based on analysis of prescriptions. The results are shown in tables after descriptive and bivariate analysis. Fisher's exact test, Bonferroni's post hoc for categorical variables and Kendall's tau correlation coefficient for continuous variables were used.

**Results:** Four hundred and forty-four prescriptions for 49 patients were analyzed. Data showed a mean age of 80.4 years, a prevalence of women (57.1 %), the main diagnoses being Alzheimer's disease and neoplasia, and prevalent length of up to 7 days. Morphine was the most used medication (15.8 mg to 20.8 mg). The oral route was predominant at the beginning of hospitalization and the subcutaneous route at the end. There was a greater dose variation in degenerative disease of the nervous system and statistical significance between length of stay (1 to 7 days) and clinical diagnosis.

**Discussion:** The sociodemographic and clinical characteristics are in line with the Brazilian epidemiological profile. The use of opioids was equivalent to that recommended and is more associated with dyspnea control. Dose variation in degenerative nervous system disease probably occurred due to the variability of diseases included in this group. The statistical significance between length of hospitalization and diagnosis can be justified by the clinical severity of the patients hospitalized.

**Keywords:** Analgesics, Opioid; Palliative Care; Hospitals, Public; Geriatrics.

### RESUMO

**Introdução:** Os pacientes em Cuidados Paliativos Geriátrico (CPG) queixam-se de dor e os opioides são os medicamentos usados para o manejo. Esse estudo visa conhecer as características sociodemográficas, clínicas e referentes ao uso de opioides nos CPG de um hospital público do Distrito Federal.

**Métodos:** Abordagem transversal a partir da análise de prescrições. Os resultados aparecem em tabelas após a análise descritiva e bivariada. Utilizou-se teste exato de Fisher, post hoc de Bonferroni para variáveis categóricas e o coeficiente de correlação tau de Kendall para variáveis contínuas.

**Resultados:** Analisou-se 444 prescrições de 49 pacientes. Os dados mostram idade média de 80,4 anos, prevalência feminina (57,1 %), diagnósticos principais de doença de Alzheimer e neoplasias, e tempo de internação prevalente de até 7 dias. A morfina foi o medicamento mais usado (15,8 mg a 20,8 mg). A via oral foi predominante no início da internação e a via subcutânea ao final. Houve variação de dose mais acentuada na doença degenerativa do sistema nervoso e significância estatística entre o tempo de internação (1 a 7 dias) com diagnóstico clínico.

**Discussão:** As características sociodemográficas e clínicas estão em conformidade com o perfil epidemiológico brasileiro. O uso de opioides mostrou-se equivalente com o recomendado e está mais associado ao controle de dispneia. A variação de dose na doença degenerativa do sistema nervoso provavelmente ocorreu devido a variabilidade de doenças incluídas neste grupo. A significância estatística entre o tempo de internação e o diagnóstico pode ser justificada pela gravidade clínica dos pacientes internados.

## INTRODUCTION

Geriatric Palliative Care (GPC) is the unification of geriatric medicine with palliative medicine. In other words, it is an approach focused on the elderly population and their families who face problems associated with life-threatening illnesses, aiming to improve patients' quality of life by preventing and relieving suffering<sup>1,2</sup>. In recent years, GPC has gained more prominence due to the aging population associated with the involvement of chronic multimorbidities, such as cardiovascular diseases, diabetes, cognitive decline, and cancer<sup>3</sup>.

Among the main symptoms affecting patients in palliative care, pain is the most common complaint reported by elderly patients and opioids are the most indicated drugs for managing this symptom. However, pain in the geriatric population is often under-treated and opioids are used restrictively by health professionals due to their adverse reactions<sup>4,5</sup>.

Proper use of opioids in the elderly requires attention to the physiological changes that are characteristic of this age group. For example, the metabolism and excretion of drugs by the body are processes that undergo significant changes with advancing age, as well as an increased sensitivity to the use of drugs. Despite this fact, the use of opioid analgesics is possible and should be used whenever necessary in order to achieve pain control, comfort, and better quality of life, commensurate with the elderly person's clinical condition<sup>3,4</sup>.

Given the fact that GPC is an emerging field of study<sup>3</sup> and considering that opioids are drugs that are little used in symptoms management in the elderly<sup>4</sup>, this study aims to understand the sociodemographic, clinical, and opioid-related characteristics in the geriatric palliative care unit of a public hospital in the Federal District of Brazil.

## METHODS

This is a six-month cross-sectional study based on the analysis of patient prescriptions in the geriatric palliative care unit of a public hospital in Brazil's Federal District. The prescriptions of inpatients were analyzed, looking at the dose and route of administration of the following opioid analgesics: morphine, methadone, and fentanyl. The sociodemographic and clinical characteristics of the patients were also assessed, considering gender, age, International Classification of Diseases (ICD-10) and length of hospitalization.

Patients admitted to the hospital's geriatric unit between September 2021 and March 2022 took part in the study. Patients were included in the study according to the following criteria: age 60 or over with severe dementia confirmed by a doctor, urinary and faecal incontinence, absence of significant verbal communication, limited speech capacity; frail

elderly over 80 years old, characterized by multimorbidities, weight loss in the last year, low physical activity, exhaustion, weakness, decreased gait speed. Patients were excluded according to the following criteria: patients with a recent stroke (less than three months) or first episode of cerebrovascular accident vegetative states, patients on any form of dialysis, using mechanical ventilation, using parenteral nutrition, and using vasoactive drugs.

Data was collected by accessing patients' electronic medical records and prescriptions through the Trakcare® system, after prior approval by the Research Ethics Committee. The doses of methadone and fentanyl were converted into morphine-equivalent doses, based on the literature<sup>6</sup>, to enable comparison and analysis of the data. All doses presented in the results are in milligrams (mg).

With this information, a descriptive analysis was carried out on all the study variables, presented in absolute numbers, proportion, mean and standard deviation. Diagnosis, age and sociodemographic characteristics, clinical characteristics and opioid use were analyzed using Fisher's exact test, followed by Bonferroni's post hoc test for categorical variables and Kendall's tau correlation coefficient for continuous variables. Data was considered significant when  $p < 0.05$ . All analyses were carried out using the IBM SPSS program, version 19.0. There are no conflicts of interest related to the publication of the study.

## RESULTS

The study analyzed 444 prescriptions from 49 inpatients between September 2021 and March 2022. The results are shown in Table 1, Table 2, Table 3, and Figure 1.

Table 1 shows the descriptive results of the sample relating to sociodemographic and clinical characteristics and opioid use. The study participants were on average 80.4 years old ( $SD \pm 9.6$ ) and 57.1% were women. With regard to clinical characteristics, the majority had a diagnosis of Alzheimer's dementia (44.9%), followed by neoplasia (22.4 %). The patients had been in the geriatric unit for up to 7 days (65.3 %). Most of them used only one opioid (96 %), with 98% using morphine. The opioid dose varied on average from 15.8 mg ( $SD \pm 13.0$ ) to 20.8 mg ( $SD \pm 18.6$ ) and changed for 53.1% of the participants. Regarding the route of administration, the oral route was the most used at the beginning of hospitalization (28.6%) and the subcutaneous route was the most used at the end of hospitalization (26.5 %). In all, 32.7 % of patients had their route of administration changed.

Figure 1 shows the variation in the opioids' doses taken by the participants according to their clinical diagnosis. There was an increase in doses on the first day of hospitalization and minimum doses, compared to doses on the last day of

**Table 1.** Sociodemographic, clinical, and opioid use characteristics of elderly patients admitted to a public hospital in Brazil's Federal District from September 2021 to March 2022.

hospitalization and maximum doses used by the participants. The graph shows that this difference was greater among patients diagnosed with degenerative diseases of the nervous system, with a variation of approximately 60 mg.

Table 2 shows the bivariate analyses between the variables and the main clinical diagnoses, dementia and degenerative diseases, and neoplasia and other diseases, showing that there was statistical significance between the length of time patients were hospitalized (1 to 7 days) and clinical diagnosis ( $p < 0.05$ ). There was a marginal association between diagnosis and the maximum dose of opioids used ( $p = 0.07$ ), as well as a higher percentage of patients using the oral route of administration ( $p = 0.05$ ). The other patient's characteristics were not significantly different.

The bivariate analysis between the variables and age showed that there was no statistically significant difference in the percentage of patients aged 80 or over with sociodemographic, clinical, and opioid use-related characteristics (Table 3).

## DISCUSSION

The descriptive results of the sociodemographic characteristics indicate an average age of 80.4 years, varying by 9.6 years, and a higher prevalence of women (57.1%) (Table 1). This profile corresponds to the projected life expectancy estimated by the Brazilian Institute of Geography and Statistics (IBGE) for 2021/2022 of  $\approx 80$  years for women and  $\approx 70$  years for men. The descriptive results of the sociodemographic characteristics indicate a mean age of 80.4 years, varying from 9.6 years to more or less, as well as showing a higher prevalence of women (57.1%) (Table 1). This profile corresponds with the life expectancy projection estimated by IBGE for 2021/2022 of  $\approx 80$  years for women and  $\approx 70$  for men<sup>7</sup>.

The clinical characteristics related to diagnosis showed a prevalence of dementia as Alzheimer's disease (44.9%), followed by neoplasia (22.4%) and degenerative diseases of the nervous system (16.3%) (Table 1). These pathologies make up the World Health Organization ranking published in 2020 of the main causes of death in the world, highlighting the relevance of chronic non-communicable diseases<sup>8</sup>. It is also described in Brazilian epidemiology, which cites neoplasia and diseases of the nervous system among the main causes of mortality in the elderly<sup>9,10</sup>.

Regarding clinical characteristics, 65.3% of participants were hospitalized for between 1 and 7 days and 20.4% for more than 15 days (Table 1). The bivariate analyses indicated that the length of hospitalization (1 to 7 days) showed a relevant result ( $p < 0.05$ ) when correlated with the diagnosis (Table 2). It is likely that the profile of the study participants, which mainly

included frail elderly people with functional dependence and severe cognitive decline, combined with the fact that invasive and disease-modifying measures were not indicated, influenced this result. In other words, the clinical severity of patients in palliative care may have favored a shorter length of stay<sup>11</sup>. Moreover, patients with longer hospitalization periods may have had pain that was difficult to control<sup>12</sup>.

With regard to the use of opioids, it was found that most patients used at least one opioid (96%), with morphine being prescribed for 98% of patients (Table 1). The use of morphine is indicated to control moderate to severe pain and dyspnea<sup>13</sup>. This result may indicate adequate management of GPC, considering morphine as an indicator of quality of death<sup>14,15</sup>. In addition, the list of Potentially Inappropriate Medications for the Elderly, or Beers Criteria, allows for the prolonged use of morphine and other strong opioids in the elderly, in cases where palliative care is indicated or for the management of moderate chronic pain<sup>16,17</sup>.

The average dose of opioids ranged from 15.8 mg (SD  $\pm 13.0$ ) to 20.8 mg (SD  $\pm 18.6$ ), 53.1% of participants adjusted their dose throughout their hospitalization and a small percentage of patients (2%) used up to three opioids (Table 1). Comparing these results with those recommended, the average dose values found are lower than those expected for opioid-naïve patients for pain control (30 mg to 60 mg per day) and are in line with the doses indicated for dyspnea control (15 mg to 30 mg per day). This may indicate a greater use of opioids for dyspnea control than for pain among the study participants. Moreover, it is also recommended to re-evaluate the opioid prescribed and adjust the daily doses according to the need to control symptoms, which would justify changing the dose in 53.1% and the use of up to three opioids in 2% of the participants<sup>6,13,18,19</sup>.

The maximum dose showed a marginal association ( $p = 0.07$ ) with diagnosis (Table 2) and the variation of doses according to diagnosis shows an increase of opioid doses on the first day of hospitalization and minimum doses, in relation to doses on the last day of hospitalization and maximum doses used mainly among patients diagnosed with degenerative diseases of the nervous system, a variation of approximately 60 mg (Figure 1). It is likely that the complexity and diversity of the diagnoses is related to the management and use of opioids found in the analysis. The term "degenerative disease of the nervous system" groups together many other diseases, such as frontotemporal dementia, progressive supranuclear palsy, corticobasal degeneration, Parkinson's disease, dementia with Lewy bodies, and others that would require their own drug management in each case, which would explain the greater variation of doses taken by the study participants<sup>20</sup>.

Regarding the route of administration, it was found that the oral route was the most used at the beginning of hospitalization (28.6%) and the subcutaneous route was the most used at the end of hospitalization (26.5%), with 32.7% of the participants changing their route of administration (Table 1). There was also a marginal association between the diagnosis and the percentage of patients who used the oral route of administration ( $p = 0.05$ ) (Table 2). This data can be explained by the suggestion of the most physiological route (oral) whenever possible, as well as the subcutaneous route being indicated as the most comfortable injectable route for patients in palliative care. Likewise, a change of route is recommended whenever necessary, depending on the worsening of the clinical condition<sup>6,18,19</sup>.

The correlation with age did not yield any relevant results, i.e., there was no significant association between the patients' age and the variables analyzed (Table 3). It is possible that the sample size evaluated in the study was not enough to establish an association<sup>21</sup>.

In general, the study revealed that the conduct related to opioid management in the hospital evaluated is in line with recommendations<sup>6,18,19</sup>, considering the dosage and characteristics of the prescription of opioid analgesics in palliative care, standing out in comparison with the use of opioids in Brazil. Brazil ranks low in the world ranking of quality of death due to, among other indicators, the small amount of opioids prescribed<sup>14</sup>. On the other hand, it was not possible to assess pain management in comparison with the doses in use and the fact that the sample size was insufficient to establish a greater number of associations<sup>21</sup>. It is therefore very important to encourage more research into the use of opioid analgesics in palliative care and geriatrics, in order to expand knowledge on the subject, and consequently, the use of opioids.

## ACKNOWLEDGMENTS

The authors wish to thank the *Escola Superior de Ciências de Saúde*, especially the Multiprofessional Residency Program in Palliative Care, for encouraging them to carry out this research, and the Health Secretariat of the Federal District of Brazil for providing the data analyzed in the study, and for the cordiality and assistance provided during its development.
